

EvenOddEscalator

Two Lean-checked machines, same chassis.

Thesis: Bounded local step does NOT imply bounded orbit. Smooth until environment says not today.

1. Stable - stays in the net - $q < 1$

- vortex cannon, tuna, diesel, pendulum, egg, fish net, containers shaken not stirred
- `orbit_prefix_mem_interval` : stays in interval for k steps
- Mass = pressure = q . Mass under feet = biggest Mcap = biggest q .

2. Unstable - escapes - $q = 1$

- EvenOddEscalator: even +3, odd +1, so two steps = +4
- `iterate_two_mul` : $\text{step}^{[2k]} n = n + 4*k \rightarrow$ unbounded
- No left compensation. Something goes right so it can go more right.

Both build with `lake build`, 0 sorry, 0 axiom beyond Mathlib.

Old science: mass tells space how to bend.

New file: System, bound, witness, drift.

```
1 lake build
```
